

Climate and Oceans Support Program in the Pacific

The Climate and Oceans Support Program in the Pacific (COSPPac) works to enhance the accessibility of essential ocean and climate information for Pacific Island nations. Through initiatives like wave climate reports, sub-seasonal to seasonal forecasts and ocean data tools, COSPPac strengthens ocean services across the region. The updated wave climate reports, based on hindcast data spanning 1979 to 2023, offer insights into regional wave climatology. These reports aim to support informed decision-making and resilience planning.

I. General Wave Climate

I.1 General Introduction

This wave climate report presents wave information for **Honikulu Passage** in Wallis and Futuna. This report contains information about wind-generated surface gravity waves, often called wind waves and swell. The wave climate is defined here as the statistics of waves conditions over a 44 year period. The report details the average wave condition (page 2 and 3), the variability of wave conditions (page 4 and 5), severe and extreme waves (page 6 to 9) and characterises the wave energy resource (Page 10). Similar wave climate reports are available for more than 200 locations around the Pacific, near important ports, large settlements, tide gauge locations and areas where the wave climate is of particular interest. Other locations in Wallis and Futuna are shown in Figure 1 (Previous page). Because little wave data exists for the Pacific, the information presented here was derived from a computer model: a regional wave hindcast.

The wave hindcast evaluated the wave conditions in the region between 1979 and 2023. The hindcast was produced by the Centre for Australian Weather and Climate Research, and updated by the Bureau of Meteorology (Australia) since 2013 onwards and focusses on the central and south Pacific with a resolution of 10 to 4 arcminutes (~20 to 8km) and therefore is accurate for offshore wave conditions. The model was constrained by the best available data and thoroughly verified against waves measurements. In the Pacific region, the wave hindcast produced reasonably good results with an average skill of 0.85 (skills between 0.8 and 0.9 are considered good, above 0.9 is considered excellent, see Table 1). For more information about the regional wave hindcast, readers should refer to Durrant et al. (2014) and Smith et al. (2020). This report was generated by a computer program created at SPC-Geoscience which analysed the output from the wave hindcast and summarised the findings. Therefore, despite our best effort, this report may contain errors and omissions and should be used with caution.

Table 1 Validation of the Wave hindcast model used to evaluate the wave climate

Island (Country)	Longitude Latitude	Depth [m]	RMS [m]	Skill	Bias [m]
Efate (Vanuatu)	168.5500 -17.8750	285	0.419	0.905	0.309
Funafuti (Tuvalu)	179.2150 -8.52500	585	0.559	0.544	0.504
Kadavu (Fiji)	177.9567 -19.3067	356	0.355	0.910	-0.097
Rarotonga (Cook Islands)	200.2717 -21.2700	300	0.413	0.895	0.087
Tongatapu (Tonga)	184.7300 -21.2370	309	0.321	0.920	-0.039
Apolima St. (Samoa)	187.8000 -13.8800	104	0.394	0.871	0.241
Upolu (Samoa)	188.7800 -14.4150	850	0.347	0.883	0.146

I. General Wave Climate (Cont.)

I.2 Average Wave Conditions

Wave condition is usually defined by the significant wave height, the peak period and the peak direction. The significant wave height is defined as the mean wave height (from trough to crest) of the highest third of the waves and correspond to the wave height that would be reported by an experienced observer. The peak period is the time interval between 2 waves of the dominant waves. The peak direction is the direction the dominant waves are coming from. Note that this document uses the nautical convention and therefore reports the direction the waves (wind) are coming from, measured clockwise from geographic North.

This page provides information about the average wave climate of **Honikulu Passage** in Wallis and Futuna. The average sea state is moderate, dominated by swell from the East. The annual mean wave height is **1.68m**, the annual mean wave direction is **111°** and the annual mean wave period is **11.61s**. Table I.2 summarize the mean wave condition for Honikulu Passage.

In the pacific, waves often comes from multiple direction and with different period at a time. In Honikulu Passage, there are often more than 8 different wave direction/period components.

Wave conditions tend to be consistent, meaning that they vary little within a few hours. The mean annual and seasonal variability are reported in Table 2. For more information on the wave climate variability refer to page 5 and 6.

Table 2 Mean wave conditions calculated between 1979 and 2023 for Honikulu Passage

Mean wave height	1.68m
Mean wave period	11.61s
Mean wave direction [° True North]	111 ° 
Mean number of wave components	7.71
Mean annual variability [m] (%)	0.08 m (4.6 %)
Mean seasonal variability [m] (%)	0.44 m (26.1 %)

II. Mean Wave Rose

II.1 Annual mean wave rose

The mean wave condition, does not describe the variety of wave height and direction that can occur in Honikulu Passage. A better representation of the variety of waves is the wave rose (Figure 2). The annual wave rose shows where waves usually come from and the size of waves associated with each direction. It is a powerful illustration of the distribution of wave height and direction. The circles (polar axis) represents how often a wave direction/height happens (i.e. the percentage of occurrence); each circle shows the 10% occurrence with the outer circle representing 30% of the time. Each wedge represents a range of direction 20 degrees wide with the center direction of each wedge displayed on the outer circle. Wave heights are split into intervals of 0.25m. Each interval is associated with a colour on the scale right of the rose.

In Honikulu Passage the wave come from many sources. The conditions are frequently moderate, almost never calm and almost never rough. The principal direction, where waves Southeast (120°).

Figure 2 Annual wave rose for Honikulu Passage. Note that direction are where the wave are coming from.

III. Wave Variation

III.1 Introduction

The wave climate is rarely constant throughout the year and seasonal changes in wind patterns across the Pacific Ocean can greatly modify the wave conditions from one season to the next. This page provides a description of these variations in Honikulu Passage. The monthly variability (or coefficient of variation) of the wave height is used to quantify these variations, in Honikulu Passage the variability of the wave height is 26.1%. Typically, locations that are mostly exposed to trade winds show the smallest variation (less than 25%). Locations exposed to the Southern Ocean swell show more monthly variation (between 25 and 30%) and locations exposed to the North Pacific swell show the most monthly variation (>30%). The monthly variability gives an idea of how the wave condition changes from one month to the next but to better understand the seasonal changes requires to look at the seasonal wave roses (figure 3).

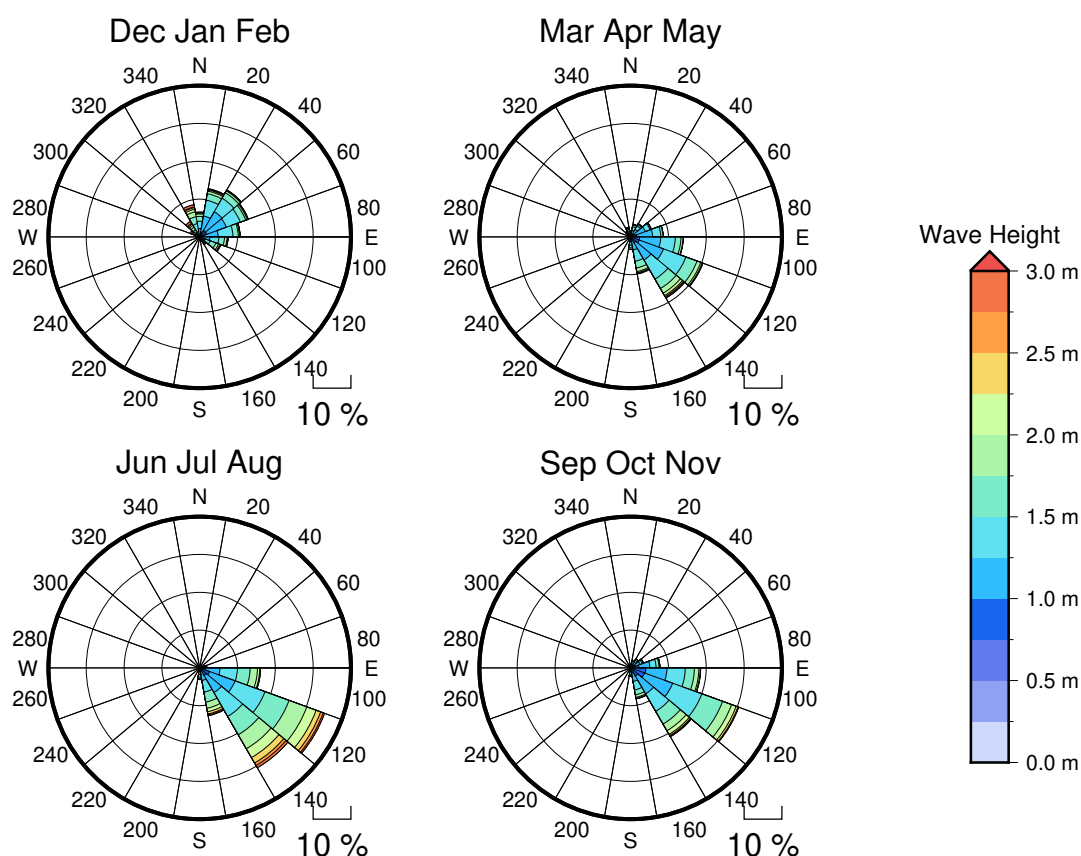

Figure 3 Seasonal wave roses for Honikulu Passage

III.2 Seasonal wave rose summary

In summer the dominant wave condition (occurring frequently) is moderate, the waves are almost never calm and seldom rough and the principal wave direction is from the Northeast (40°). In autumn the dominant wave condition (occurring frequently) is moderate, the waves are almost never calm and almost never rough and the principal wave direction is from the Southeast (120°). In winter the dominant wave condition (occurring frequently) is moderate, the waves are almost never calm and seldom rough and the principal wave direction is from the Southeast (120°). In spring the dominant wave condition (occurring frequently) is moderate, the waves are almost never calm and almost never rough and the principal wave direction is from the Southeast (120°).

III. Wave Variation (Cont.)

III.3 Monthly wave height, period and direction

The monthly wave height, period and direction show the seasonal changes in the wave parameters with more details on the transition between seasons. The average wave height during calm periods (10% of the lowest wave height) and large swell events (10% of the largest wave heights) also changes with seasons. Figure 4 can help in finding the best month for servicing or installing offshore structures and moorings.

Figure 4 Monthly wave height (Black line), wave period (Red line) and wave direction (arrows). The grey area represents the range of wave height between calm periods (10% of lowest wave height) and large wave events (10% of highest wave height)

III.4 Annual wave height, period and direction

Waves change from month to month with the seasons but they also change from year to year with climate oscillations. Typically these changes are smaller than the seasonal changes but can be important during phenomenon such as El Niño. In Honikulu Passage, the inter-annual variability (or coefficient of variation) for wave height is 4.6%, The Pacific average region variability is typically 7%. In Honikulu Passage the mean annual wave height has remained relatively unchanged since 1979. The mean annual wave height in Honikulu Passage is correlated with the Southern Oscillation Index ($r=-0.50$, $p<0.05$), which is a measure of the development and intensity of El Niño or La Niña events in the Pacific. The 1997/1998 El Niño greatly affected the wave climate in the Pacific region and in most islands a dramatic change in the wave patterns could be observed (Figure 5).

Figure 5 Annual wave height (Black line), wave period (Red line) and wave direction (arrows). The grey area represents the range of wave height between calm periods (10% of lowest wave height) and large wave events (10% of highest wave height)

IV. Large and Severe Waves

IV.1 Introduction

From time to time the waves become larger to a point where they can cause erosion of the beaches and inundation of the shore. Large wave are waves that exceed the 90th percentile of the wave height. In other words large wave occur 10% of the time (37 days in a year). Large wave are typically the largest event expected each month. Large wave rarely cause damage on the coast or inundation but water activities during large wave events can be hazardous. Large wave events do cause coastal inundation and erosion when they occur at the same time than large spring tide such as perigean spring tides (also called king tides). In Honikulu Passage the threshold for large waves is 2.2m.

Severe waves are less common than large wave. They are the waves that occur less than 1% of the time (4 days in a year). Severe waves typically occur once or twice in a year. Severe waves can be associated with coastal erosion and inundation especially if they occur during spring tides and water activities are hazardous on the coast during these events. In Honikulu Passage the threshold for severe waves is 3.2m.

Large and severe waves can be generated by different weather events such as, cyclones, distant extra tropical storms and fresh trade winds. The direction and period of the waves are telltale of the origin of the large waves. This information can be derived from the large, severe and extreme wave rose (Figure 6). In Honikulu Passage, the dominant direction for wave height larger than 2.2m is from the Southeast (140°).

Large and severe wave rose:

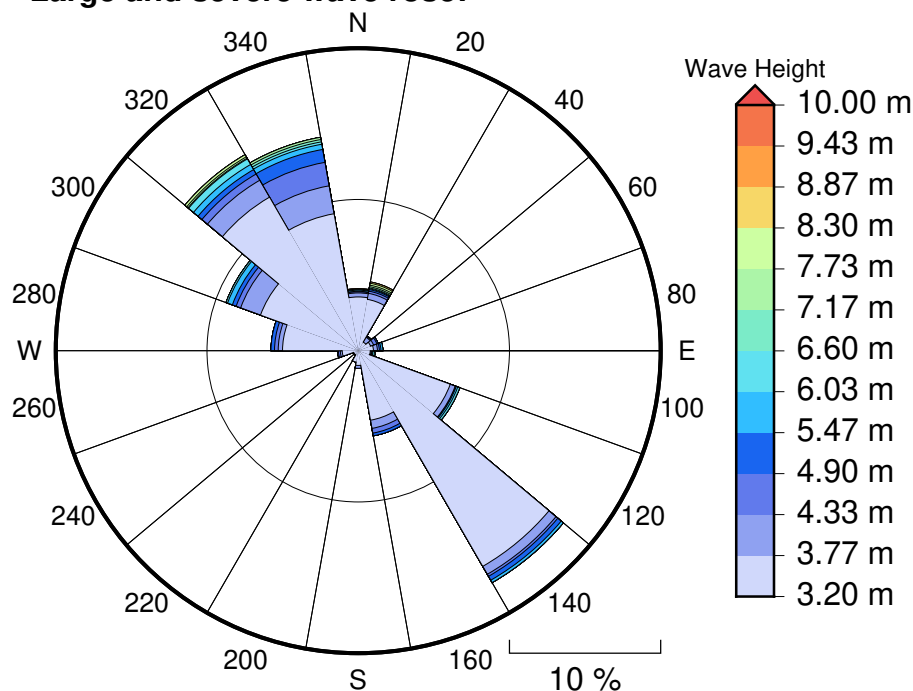

Figure 6 Large, severe and extreme wave roses for Honikulu Passage

IV. Large and Severe Waves (Cont.)

IV.2 Large wave variability

Larger waves can be generated by different meteorological phenomena such as tropical cyclones, extra-tropical storm or fresh trade wind events. These meteorological events are very dependent on the seasons and so does the large waves. In Honikulu Passage large waves are bigger in winter(Jun). Large waves are also present during other seasons and the monthly variability of the large wave threshold (90th percentiles) for Honikulu Passage is 8% (Figure 7).As mean wave height varies from year to year so does the larger waves. In Honikulu Passage the annual variability for the large wave threshold is 6% (Figure 8).

Figure 7 Monthly variation in large waves (90th percentile)(lower curve), severe waves (99th percentile) (middle curve) and the largest wave(upper curve) in Honikulu Passage.

Figure 8 Annual variation in large waves (90th percentile)(lower curve), severe waves (99th percentile) (middle curve) and the largest wave(upper curve) in Honikulu Passage.

V. Extreme waves

V.1 Largest events

A list of the 30 largest wave events is presented in table 3 with the ranking, the date (UTC time), wave height, wave period and direction at the peak of the event. The largest event that reached Honikulu Passage since 1979 was on the 14-03-2010 and exceeded 10m which is considered high . All the listed events have a wave height higher than 4m which is considered rough . The list of the 30 largest events can be used to calculate the probability of occurrence of wave event larger than the average largest annual wave height. Such analysis, called an extreme wave analysis, is presented in the next page.

Table 3 List of the 30 largest wave events in Honikulu Passage .

30 largest events				
Rank	Date	Height (m)	Period (s)	Dir. (°)
1	14-03-2010	9.99	14	2 ↓
2	17-01-2020	8.84	14	320 ↘
3	15-12-2012	8.51	12	357 ↓

V. Extreme waves (Cont.)

V.2 Extreme wave analysis

Extreme wave analysis are used to assess the probability of occurrence of wave events larger than the severe wave height. It is often used to evaluate the vulnerability of communities to coastal inundation and to decide how high a seawall or a jetty needs to be built. Extreme wave analysis is a statistical analysis that looks at the distribution of past wave events and extrapolates (predict) the probability of occurrence of unusually large events that may have never been recorded. The probability of an event to occur within a year is often presented as an Annual Return Interval (ARI). The ARI is the probability of an event to occur within a year. For example the probability of a 100 year ARI event to occur within any given year is 1%. Similarly the probability of a 50 year ARI event to occur within any given year is 2%.

The analysis completed for Honikulu Passage was done by defining a threshold of severe heights and fitting a Generalised Pareto Distribution (hereafter GPD). The optimum threshold was selected at 3.17m. In the 40 year wave hindcast 139 wave events have reached or exceeded this threshold. The GPD was fitted to the largest wave height reached during each of these events (Figure 9). Extreme wave analyses are a very useful tool but are not always accurate because the analysis is very sensitive to the data available, the type of distribution fitted and the threshold used. For example, this analysis does not accurately account for Tropical Cyclone waves. More in-depth analysis is required to obtain results fit for designing coastal infrastructures and coastal hazards planning.

Figure 9 Extreme wave distribution for Honikulu Passage. The crosses represents the wave events that occurred since 1979. The plain line is the statistical distribution that best fit the past wave events. The dotted line show the upper and lower high confidence of the fit, there is a 95% chance that the fitted distribution lie between the two dashed lines.

Table 4 Summary of the results from extreme wave analysis in Honikulu Passage .

Large wave height (90 th percentile)	2.19 m
Severe wave height (99 th percentile)	3.20 m
1 year ARI wave height	4.00 m
10 year ARI wave height	7.01 m
20 year ARI wave height	8.46 m
50 year ARI wave height	10.96 m
100 year ARI wave height	13.41 m

VI. Wave energy

VI.1 Introduction

Ocean waves are often cited as an appealing renewable energy resource because waves are a dense energy resource that is consistently present in some location. However, extracting wave energy is challenging because of the oscillating nature of waves and because of the harshness of the ocean environment. Yet some wave energy converters (e.g. Pelamis device) have reached a level of efficiency and reliability that is sufficient to generate electricity at a competitive cost if the resource is sufficient.

The wave energy resource is usually summarised by the mean annual wave energy flux (wave power). Typically locations with a mean annual energy flux above 7 kW/m should further investigate the feasibility of wave energy converters. In Honikulu Passage the mean annual energy flux is 13.0kW/m.

Further site investigations should include a detailed assessment of the resource, environment and requirements for the most appropriate device for the site. The Pelamis device, a former prominent wave energy converter, can be used as a benchmark to compare between potential wave energy sites and between locations. In the Pacific, the total lifetime cost of a single device like the Pelamis is expected to be between \$US6,318,000 and \$US14,104,000.

In order to calculate the energy generated by a single device, similar to the Pelamis, the probability of occurrence of all sea states has to be calculated. This is done by calculating the percentage of time that a particular combination of wave height and wave period occur. The occurrence of sea states for Honikulu Passage is presented in figure 10. This can then be combined with estimated power outputs from a Pelamis device for each of these sea states. In Honikulu Passage the average annual energy output of a single device similar to the pelamis is expected to be 657MWh. Combined with the expected capital cost of a single device the cost of electricity generation of wave energy from a single Pelamis device in Honikulu Passage is between 385\$US/MWh 859\$US/MWh.

Wave energy converters in Honikulu Passage may be economical and able to compete with other source of energy. Further investigations are highly recommended.

Figure 10 Occurrences of sea states in Honikulu Passage .

VIII. Wind

VIII.1 Introduction

Wind is the origin of all waves and although swells are created by distant wind events, local winds can significantly affect the local waves. In Honikulu Passage the prevailing wind is dominated by South Easterly trade winds, with a mean wind speed of 5.83ms^{-1} (11.33knts) from the 96° . Figure 11 shows the wind rose for Honikulu Passage and Figure 12 shows the monthly mean wind speed and direction. Note that the results presented here use the nautical convention: directions shown are the directions the wind is blowing from.

Figure 11 Annual wind rose for Honikulu Passage. Note that directions are where the wind is **coming** from.

Figure 12 Monthly wind speed (Black line) and wind direction (arrows).

Glossary

Autumn

Autumn is the transition season between summer (wet season) and winter (dry season), best noticed by low wind speed and change in wind direction and warm seas. This is typically when the largest cyclone occur.

Climate oscillation

A climate oscillation or climate cycle is any recurring cyclical oscillation within global or regional climate, and is a type of climate pattern.

El Niño

El Niño events are large climate disturbances which are rooted in the tropical Pacific Ocean that occur every 3 to 7 years. They have a strong impact on the weather around the tropical Pacific, and some climatic influence on half of the planet.

Hindcast (wave)

The prediction of wave characteristics using meteorological information combined in a model, this is often used when measurements of these features are not available.

Mean number of wave components

Represents the mean number of wave events occurring at any given time. These values describe the complexity of the wave climate.

Mean annual variability

Is the standard deviation in annual mean wave height. In other word, it is the average changes in the mean wave height expected from one year to another.

Mean seasonal variability

Is the standard deviation in the wave height within a year. In other word it is the average changes in wave height from one season to another

Offshore Zone

Coastal waters to the seaward of the nearshore zone. Swell waves in the offshore zone are unbroken and their behaviour is not influenced by the seabed.

Spring

Spring is the transition season between winter (dry season) and summer (wet season) during which we see days getting longer, temperatures warming.

Summer

Time of year when part of the Earth receives the most daylight: In the Pacific. Summer is often associated with increase rainfall and often referred to as the wet season.

Swell Waves

Wind waves that have travelled far from the area of generation (fetch). They are often uniform and orderly appearance characterised by regularly spaced wave crests.

Glossary (Cont.)

Wave climate

Wave climate is the average wave condition in a given region over a long period of time, usually 30 years. It is the measure of the average pattern of variation in "variables", such as wave height, wave period, and wave direction. As an example, seasonal variability in significant wave height may be characterized by calculating the monthly mean significant wave heights from several years of measurements.

Wave Direction

The direction from which ocean waves approach a location (Following the nautical convention). Generally, the principal wave direction is represented by the direction of the principal wave component.

Wave Height

The vertical distance between a wave crest and the next trough. The significant wave height is defined as the mean wave height (from trough to crest) of the highest third of the waves and correspond to the wave height that would be reported by an experienced observer.

Wave Period

The time taken for consecutive wave crests or wave troughs to pass a given point. The peak period is the time interval between 2 waves of the dominant wave component.

Wave Power

The rate at which wave energy is transmitted in the direction of wave propagation. Normally expressed in kilowatts per metre of wave crest length.

Wave rose

The annual wave rose shows where waves usually come from and the size of waves associated with each direction. It is a powerful illustration of the distribution of wave height and direction.

Wind Waves

The waves initially formed by the action of wind blowing over the sea surface. Wind waves are characterised by a range of heights, periods and wave lengths. As they leave the area of generation (fetch), wind waves develop a more ordered and uniform appearance and are referred to as swell or swell waves.

Winter

Time of year when part of the Earth receives the least daylight. In the Pacific it is often associated with a decrease in rainfall and often referred to as the dry season.
